

BOYD ARG Backend n8n Workflow Architecture

Key Features of the BOYD ARG Backend Architecture

- Centralized Orchestration**

The ARG Orchestrator serves as the central hub, routing requests between specialized services and managing system-wide operations like authentication, authorization, and service health monitoring.
- Specialized Services**

Each component focuses on a specific aspect of the ARG system: Narrative Engine for story management, Player Tracking for user progression, Timeline Management for parallel narratives, and more.
- Purpose-Built Databases**

Different database types optimize storage for specific use cases: Graph databases for narrative relationships, relational databases for player state, and time-series databases for events and scheduling.
- API-First Design**

All functionality is exposed through well-defined API endpoints, enabling seamless integration with the BOYD frontend components and third-party services like WHOP Marketplace and LTX Studio.
